

Name : Shubham Lad

Subject: Design and implementation of Compilers

Class: MSC-I (Computer Science) Semester 2

Exam Seat no: 512

Academic Year: 2022-2023

S. No	Name Of Experiment	Date	Sign
1.	Tokenizing a file		
2.	Implementation of Lexical Analyzer using Lex Tool.		
3.	Study the LEX and YACC tool and Evaluate an arithmetic expression with parentheses, unary and binary operators using Flex and Yacc (CALCULATOR).		
4.	Using JFLAP, create a DFA from a given regular expression		
5.	Create LL(1) parse table for a given CFG and hence Simulate LL(1) Parsing.		
6.	Using JFLAP create SLR(1) parse table for a given grammar. Simulate parsing and output the parse tree proper format.		
7.	Write functions to find FIRST and FOLLOW of all the variables.		
8.	Read a regular expression in standard form and check its validity by converting it to postfix form. Scan a string and check whether the string matches against the given regular expression or not.		

Hardware and Software Requirement

1. Software Requirement:

Turbo C / C++ compiler.

Download from following links:

http://www.megaleecher.net/Download_Turbo_For_Windows

LEX tool--[flex-2.5.4a-1.exe](#)

YACC tool--[bison-2.4.1-setup.exe](#)

Experiment – 1

Tokenizing a file using C

Aim: (Tokenizing). A program that reads a source code in C/C++ from an unformatted file and extract various types of tokens from it (e.g. keywords/variable names, operators, constant values).

Description: Lexical analysis is the process of converting a sequence of characters (such as in a computer program or web page) into a sequence of tokens (strings with an identified “meaning”). A program that perform lexical analysis may be called a lexer, tokenizer or scanner.

Lexical Analysis - Scanning

Token

A token is a structure representing a lexeme that explicitly indicates its categorization for the Purpose of parsing. A category of token is what in linguistics might be called a part-of-speech. Examples of token categories may include “identifier” and “integer literal”, although the set of Token differ in different programming languages. The process of forming tokens from an input stream of characters is called tokenization. Consider this expression in the C programming language: `Sum=3 + 2;`

Tokenized and represented by the following table:

Lexeme	Token category
Sum	“identifier”
=	“assignment operator”
3	“integer literal”
+	“addition operator”
2	“integer literal”
;	“end of the statement”

Source code:

```
import nltk
# import RegexpTokenizer() method from nltk
from nltk.tokenize import RegexpTokenizer
# Create a reference variable for Class RegexpTokenizer
r tk = RegexpTokenizer('\s+', gaps = True)
# Create a string input str = "I love to study Compiler code in Python"
# Use tokenize method
tokens = tk.tokenize(str)
print(tokens)
```

Output:

```
=====
['I', 'love', 'to', 'study', 'Compiler', 'code', 'in', 'Python']
>>> |
```

Experiment 2

Implementation of Lexical Analyzer using Lex Tool

Aim: (Tokenizing) Use Lex and yacc to extract tokens from a given source code.

Description:

- A language for specifying lexical analyzer.
- There is a wide range of tools for construction of lexical analyzer. The majority of these tools are based on regular expressions.
- The one of the traditional tools of that kind is lex.

Lex:-

- The lex is used in the manner depicted. A specification of the lexical analyzer is preferred by creating a program lex.l in the lex language.
- Then lex.l is run through the lex compiler to produce a 'c' program lex.yy.c.
- The program lex.yy.c consists of a tabular representation of a transition diagram constructed from the regular expression of lex.l together with a standard routine that uses table to recognize lexemes.
- Lex.yy.c is run through the 'C' compiler to produce an object program a.out, which is the lexical analyzer that transforms an input stream into a sequence of tokens.

Algorithm:

1. First, a specification of a lexical analyzer is prepared by creating a program lex.l in the LEX language.
2. The Lex.l program is run through the LEX compiler to produce an equivalent code in C language named Lex.yy.c
3. The program lex.yy.c consists of a table constructed from the Regular Expressions of Lex.l, together with standard routines that use the table to recognize lexemes.
4. Finally, lex.yy.c program is run through the C Compiler to produce an object program a.out, which is the lexical analyzer that transforms an input stream into a sequence of tokens.

Program:

```
lexp.l

Experiment-3

Study of LEX and YACC Tool

Aim: Study the LEX and YACC tool and Evaluate an arithmetic expression with parentheses, unary and binary operators using Flex and Yacc. [Need to write yylex() function and to be used with Lex and yacc.].

Description:

LEX-A Lexical analyzer generator:

Lex is a computer program that generates lexical analyzers ("scanners" or "lexers"). Lex is commonly used with the yacc parser generator.

Lex reads an input stream specifying the lexical analyzer and outputs source code implementing the lexer in the C programming language

1. A lexer or scanner is used to perform lexical analysis, or the breaking up of an input stream into meaningful units, or tokens.
2. For example, consider breaking a text file up into individual words.
3. Lex: a tool for automatically generating a lexer or scanner given a lex specification (.l file).

Structure of a Lex file

The structure of a Lex file is intentionally similar to that of a yacc file; files are divided up into three sections, separated by lines that contain only two percent signs, as follows:

Definition section:

%%

Rules section:

%%

C code section:

<statements>

- The **definition section** is the place to define macros and to import header files written in C. It is also possible to write any C code here, which will be copied verbatim into the generated source file.
- The **rules section** is the most important section; it associates patterns with C statements. Patterns are simply regular expressions. When the lexer sees some text in the input matching a given pattern, it executes the associated C code. This is the basis of how Lex operates.

- The **C code section** contains C statements and functions that are copied verbatim to the generated source file. These statements presumably contain code called by the rules in the rules section. In large programs it is more convenient to place this code in a separate file and link it in at compile time.

Description:-

The lex command reads File or standard input, generates a C language program, and writes it to a file named lex.yy.c. This file, lex.yy.c, is a compilable C language program. A C++ compiler also can compile the output of the lex command. The -C flag renames the output file to lex.yy.C for the C++ compiler. The C++ program generated by the lex command can use either STDIO or IOSTREAMS. If the cpp define _CPP_IOSTREAMS is true during a C++ compilation, the program uses IOSTREAMS for all I/O. Otherwise, STDIO is used.

The lex command uses rules and actions contained in File to generate a program, lex.yy.c, which can be compiled with the cc command. The compiled lex.yy.c can then receive input, break the input into the logical pieces defined by the rules in File, and run program fragments contained in the actions in File.

The generated program is a C language function called yylex. The lex command stores the yylex function in a file named lex.yy.c. You can use the yylex function alone to recognize simple one-word input, or you can use it with other C language programs to perform more difficult input analysis functions. For example, you can use the lex command to generate a program that simplifies an input stream before sending it to a parser program generated by the yacc command. The yylex function analyzes the input stream using a program structure called a finite state machine. This structure allows the program to exist in only one state (or condition) at a time. There is a finite number of states allowed. The rules in File determine how the program moves from one state to another. If you do not specify a File, the lex command reads standard input. It treats multiple files as a single file.

Note: Since the lex command uses fixed names for intermediate and output files, you can have only one program generated by lex in a given directory.

Regular Expression Basics

. : matches any single character except \n
* : matches 0 or more instances of the preceding regular expression
+ : matches 1 or more instances of the preceding regular expression
? : matches 0 or 1 of the preceding regular expression
| : matches the preceding or following regular expression
[] : defines a character class
() : groups enclosed regular expression into a new regular expression
“...”: matches everything within the “ “ literally

Special Functions

- yytext
 - where text matched most recently is stored
- yyleng
 - number of characters in text most recently matched
- yylval
 - associated value of current token
- yymore()
 - append next string matched to current contents of yytext
- yyless(n)
 - remove from yytext all but the first n characters
- unput(c)
 - return character c to input stream
- yywrap()
 - may be replaced by user
 - The yywrap method is called by the lexical analyser whenever it inputs an EOF as the first character when trying to match a regular expression

Files

y.output--Contains a readable description of the parsing tables and a report on conflicts generated by grammar ambiguities.

y.tab.c--- Contains an output file.

y.tab.h---- Contains definitions for token names.

yacc.tmp--- Temporary file.

yacc.debug-- Temporary file.

yacc.acts--- Temporary file.

/usr/ccs/lib/yaccpar- Contains parser prototype for C programs.

/usr/ccs/lib/liby.a-- Contains a run-time library.

YACC: Yet Another Compiler-Compiler

Yacc is written in portable C. The class of specifications accepted is a very general one: LALR(1) grammars with disambiguating rules.

Basic specification

Names refer to either tokens or non-terminal symbols. Yacc requires tokens names to be declared as such. In addition, for reasons discussed in section 3, it is often desirable to include the lexical analyzer as part of the specification file, I may be useful to include other programs as well. Thus, the sections are separated by double percent “%%” marks. (the percent “%” is generally used in yacc specifications as an escape character). In other words, a full specification file looks like.

In other words a full specification file looks like

Declarations

%%

Rules

%%

Programs

The declaration section may be empty. More over if the programs section is omitted, the second %%mark may be omitted also thus the smallest legal yacc specification is

%%

Rules

Blanks, tabs and newlines are ignored except that they may not appear in names or multi-character reserved symbols. Comments may appear wherever legal, they are enclosed in /*...*/ as in C and PL/I

The rules section is made up of one or more grammar rule has the form:A:BODY:

USING THE LEX PROGRAM WITH THE YACC PROGRAM

The Lex program recognizes only extended regular expressions and formats them into character packages called tokens, as specified by the input file. When using the Lex program to make a lexical analyzer for a parser, the lexical analyzer (created from the Lex command) partitions the input stream. The parser(from the yacc command) assigns structure to the resulting pieces. You can also use other programs along with programs generated by Lex or yacc commands.

A token is the smallest independent unit of meaning as defined by either the parser or the lexical analyzer. A token can contain data, a language keyword, an identifier or the parts of language syntax.

The yacc program looks for a lexical analyzer subroutine named yylex, which is generated by the lex command. Normally the default main program in the Lex library calls the yylex subroutines. However if the yacc command is loaded and its main program is used, yacc calls the yylex subroutines. In this case each Lex rule should end with:

return (token);

Where the appropriate token value is returned

The yacc command assigns an integer value to each token defined in the yacc grammar file through a #define preprocessor statement.

The lexical analyzer must have access to these macros to return the tokens to the parser. Use the yacc -d option to create a y.tab.h file and include the y.tab.h file in the Lex specification file by adding the following lines to the definition section of the Lex specification file:

```
%{  
#include "y.tab.h"  
%}
```

Alternatively you can include the lex.yy.c file the yacc output file by adding the following lines after the second %% (percent sign, percent sign) delimiter in the yacc grammar file:

```
#include "lex.yy.c"
```

The yacc library should be loaded before the Lex library to get a main program that invokes the yaccparser. You can generate Lex and yacc programs in either order.

Evaluating Arithmetic Expression using different Operators (Calculator)

Algorithm:

- 1) Get the input from the user and Parse it token by token.
- 2) First identify the valid inputs that can be given for a program.
- 3) The Inputs include numbers, functions like LOG, COS, SIN, TAN, etc. and operators.
- 4) Define the precedence and the associativity of various operators like +, -, /, * etc.
- 5) Write codes for saving the answer into memory and displaying the result on the screen.
- 6) Write codes for performing various arithmetic operations.
- 7) Display the possible Error message that can be associated with this calculation.
- 8) Display the output on the screen else display the error message on the screen.

Program:

CALC.L

```
%{  
#include <stdio.h>  
#include <stdlib.h>  
void yyerror(char *);
```

```

#include
"y.tab.h"int
yyval;
%}
%%

[a-z]    {yyval=*yytext='&';    return
VARIABLE;}          [0-9]+

void yyerror(char
*);int sym[26];
%}
%%

PRO
G:
PROG STMT '\n'
;
STMT: EXPR {printf("\n %d", $1);}
| VARIABLE '=' EXPR {sym[$1] = $3;}
;
EXPR: INTEGER

```

```
| VARIABLE {$$ = sym[$1];}  
| EXPR '+' EXPR {$$ = $1 + $3;}  
| '(' EXPR ')' {$$ = $2;}  
%%
```

```
void yyerror(char *s)  
{  
printf("\n %s",  
s);return;  
}  
int main(void)  
{  
printf("\n Enter the  
Expression:");yyparse();  
return 0;  
}
```

Output:

```
$ lex calc.l  
$ yacc -d calc.y  
$ cc y.tab.c lex.yy.c -ll -ly -lm  
$ ./a.out  
Enter the Expression: ( 5 +  
4 ) * 3 Answer: 27
```

Experiment-4

Using JFLAP, create a DFA from a given regular expression

Aim: Using JFLAP, create a DFA from a given regular expression. All types of error must be checked during the conversion.

What is JFLAP: -

JFLAP program makes it possible to create and simulate automata. Learning about automata with pen and paper can be difficult, time consuming and error-prone. With JFLAP we can create automata of different types and it is easy to change them as we want. JFLAP supports creation of DFA and NFA, Regular Expressions, PDA, Turing Machines, Grammars and more.

Setup: -

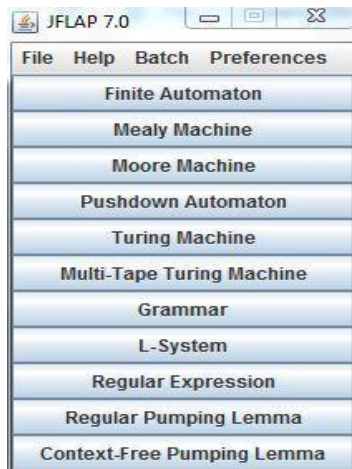

JFLAP is available from the homepage: (www.JFLAP.org). From there press “Get FLAP” and follow the instructions. You will notice that JFLAP have a .JAR extension. This means that you need Java to run JFLAP. With Java correctly installed you can simply select the program to run it. You can also use a command console run it from the files current directory with, `Java -jar JFLAP.jar`.

Using JFLAP: -

When you first start JFLAP you will see a small menu with a selection of eleven different automata and rule sets. Choosing one of them will open the editor where you create chosen type of automata. Usually you can create automata containing states and transitions but there is also creation of Grammar and Regular Expression which is made with a text editor.

DFA from a given regular expression: -

First, we need to select Regular Expression from the JFLAP Menu.

Now you should have an empty window in front of you. You will have a couple of tools and features at your disposal.

The toolbar contains six tools, which are used to edit automata.

Attribute Editor Tool, changes properties and position of existing states and transitions.

State Creator Tool, creates new states.

Transition Creator Tool, creates transitions.

Deletion Tool, deletes states and transitions.

Undo/Redo, changes the selected object prior to their history.

Regular Expressions can be typed into JFLAP to be converted to an NFA

Choose Regular Expression in the main menu, then just type the expression in the textbox.
Definitions for Regular Expressions in JFLAP:

- **Kleene Star**
- + **Union**
- **! Empty String**

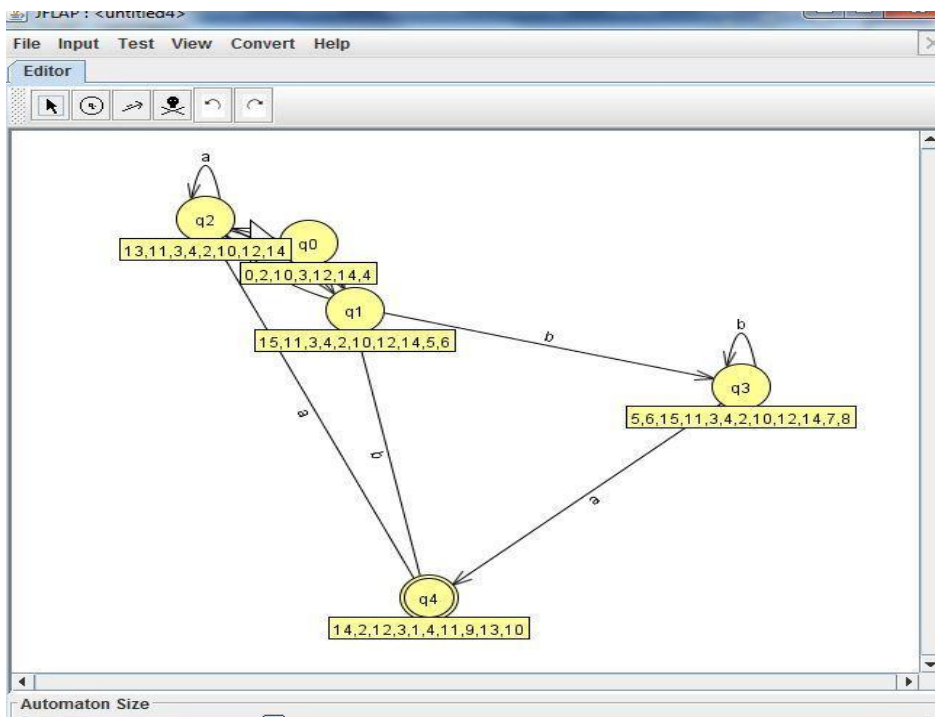

Correctly written expressions can then be converted to an NFA. To convert your expression select Convert → Convert to NFA. The conversion will begin with two states and a transition with your Regular Expression. With the (D)e-expressionify Transition tool you can break down the Regular Expression into smaller parts. Each transition will contain a sub expression. The next step is to link every rule with lambda transitions. Add new transition between states that should be connected with the Transition Tool. If you are unsure what to do you can select Do Step to automatically make the next step. If you want the NFA immediately Do All creates the whole NFA for you.

You can notice how the conversion differs depending on how the Regular Expression looks. For example the expression a^+b results in a fork, where either 'a' or 'b' can be chosen.

Now finally convert NFA to DFA:-

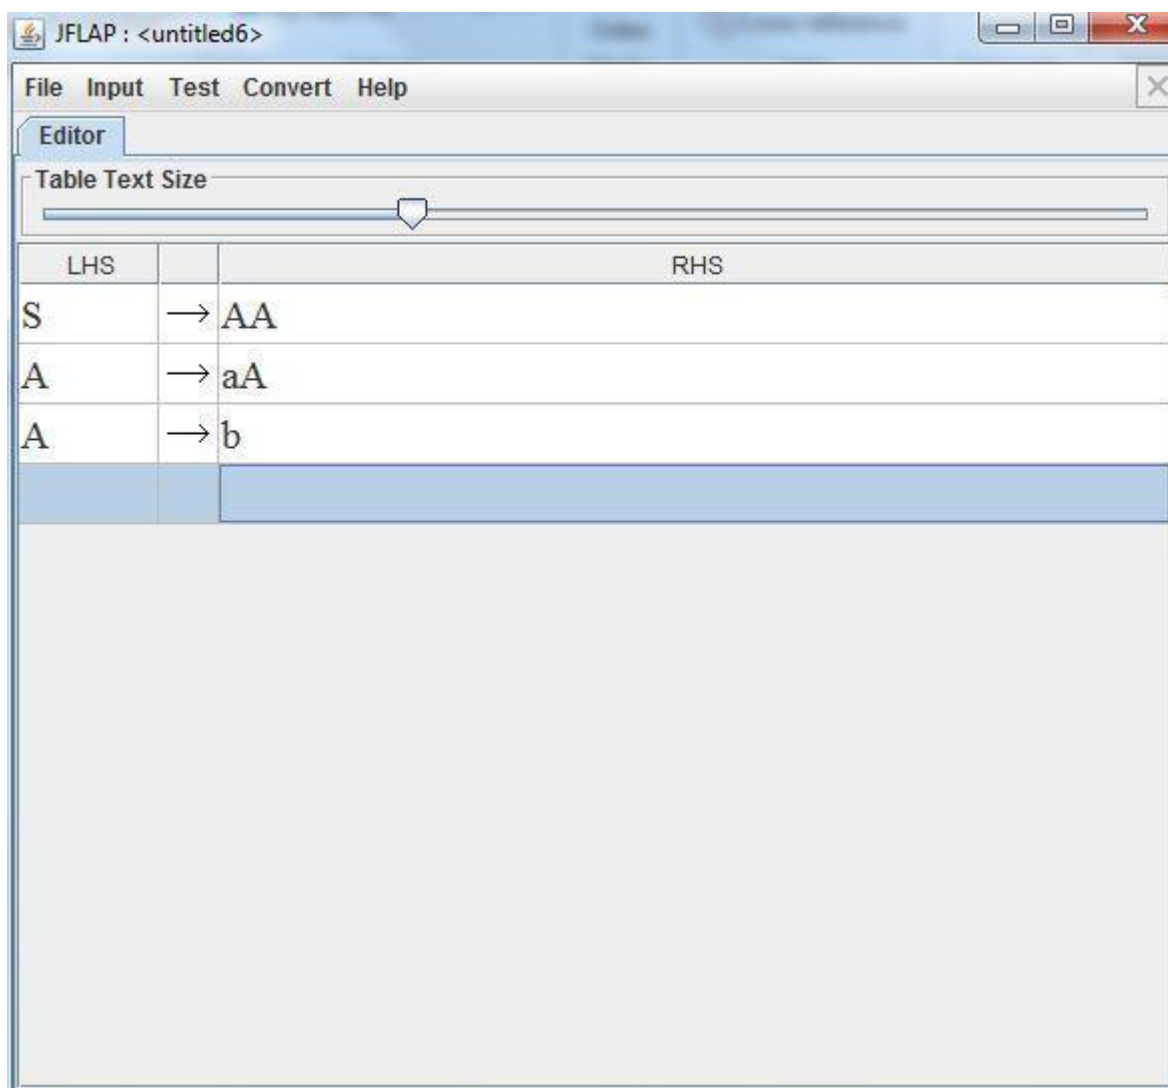

Experiment-5

Create LL(1) parse table for a given CFG and hence Simulate LL(1) Parsing

Aim: Using JFLAP create LL(1) parse table for a given CFG and hence Simulate LL(1) parsing

Implementation: -

Step 1. Choose the grammar from JFLAP and insert grammar you want to create LL(1) parsing table.

Step 2: - Select the Input from Menu and select Build LL(1) parsing table from it.

Parse table complete. Press "parse" to use it.

	FIRST	FOLLOW
A	{ a, b }	{ a, b, \$ }
S	{ a, b }	{ \$ }

	a	b	\$
A	aA	b	
S	AA	AA	

Step 3: - Now select parse to use that table to create parse tree from it.

Input: aba
Input Remaining: a\$
Stack: A

LHS	RHS
S	→ AA
A	→ aA
A	→ b

```

graph TD
    S((S)) --> A1((A))
    S --> A2((A))
    A1 --> a1((a))
    A1 --> A3((A))
    A3 --> b((b))
    A2 --> A4((A))
    
```

Replacing A with aA.

Result:- We create LL(1) parse table for a given CFG and hence Simulate LL(1) parsing

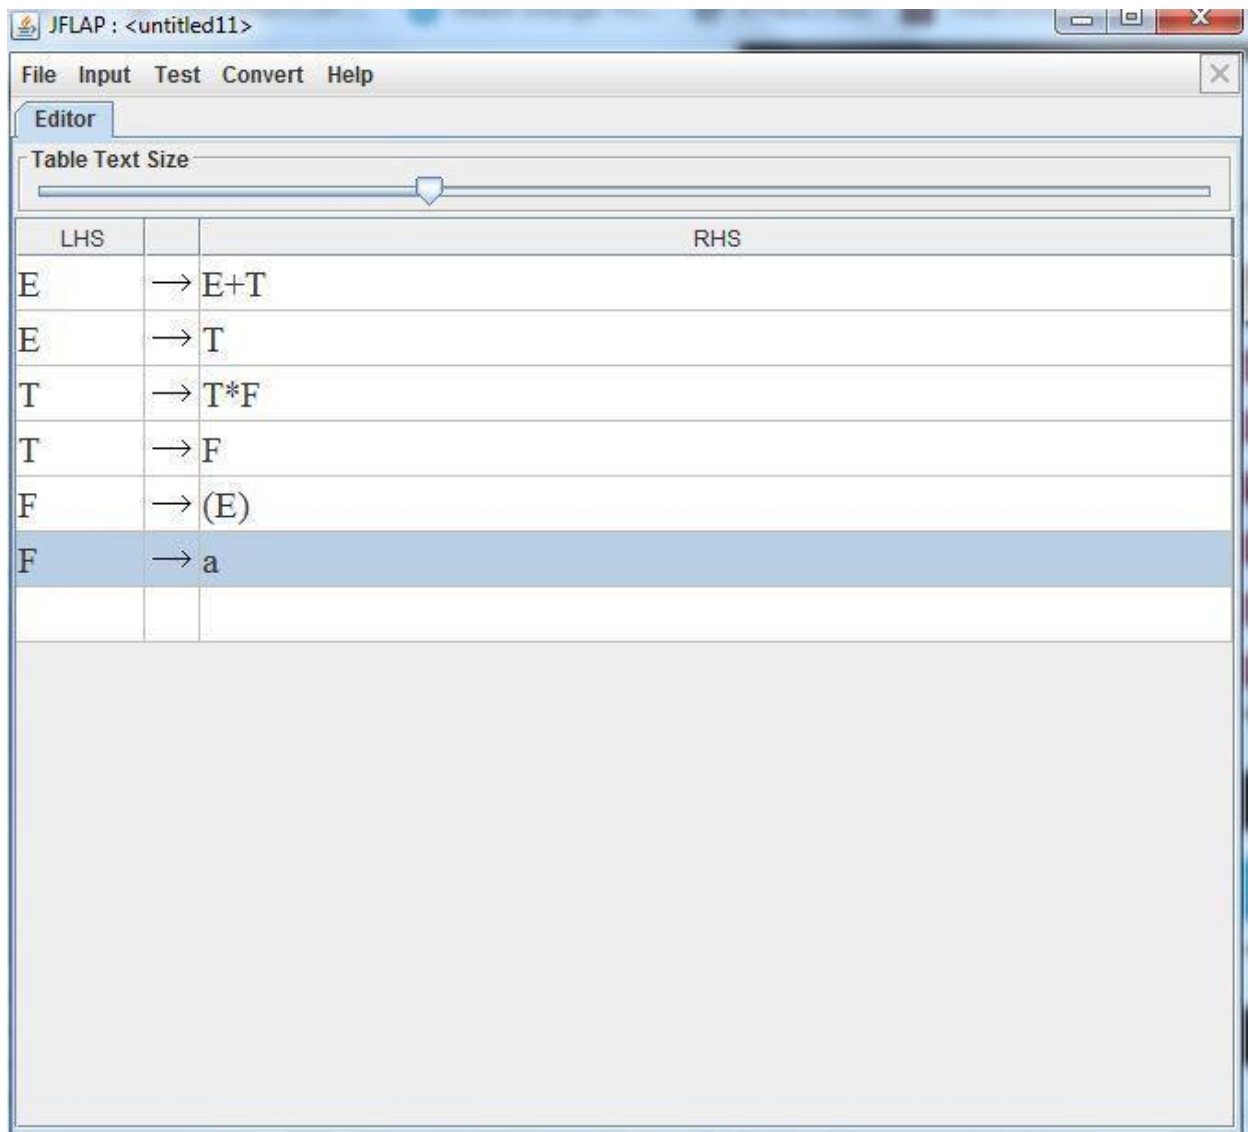

Experiment-6

Create SLR(1) parse table for a given grammar

Aim: Using JFLAP create SLR(1) parse table for a given grammar. Simulate parsing and output the parsetree proper format.

Implementation: -

Step 1: - Choose the grammar from JFLAP and insert grammar you want to create SLR(1) parsing table.

Step 2: - Select the Input from Menu and select Build SLR (1) parsing table from it.

Parse table complete. Press "parse" to use it.

	FIRST	FOLLOW
E	{ a, (}	{ \$,), + }
F	{ a, (}	{ \$,), *, + }
T	{ a, (}	{ \$,), *, + }

	()	*	+	a	\$	E	F	T
0	s1				s5		2	3	4
1	s1				s5		6	3	4
2				s7		acc			
3		r4	r4	r4					
4		r2	s8	r2					
5		r6	r6	r6					
6		s9		s7					
7	s1				s5			3	10

Step 3: - Now select parse to use that table to create parse tree from it.

Table Text Size

Start Step Noninverted Tree

Input: a*a+a
Input Remaining: \$
Stack: E0

LHS	RHS
E'	→ E
E	→ E+T
E	→ T
T	→ T*F
T	→ F
F	→ (E)
F	→ a

String accepted

Result :- We created SLR(1) parse table for a given grammar and Simulated parsing and output the parse tree proper format.

Experiment-7

FIRST and FOLLOW of all the variables

Aim: Write a suitable data structure to store a Context Free Grammar. Prerequisite is to eliminate leftrecursion from the grammar before storing. Write functions to find FIRST and FOLLOW of all the variables. [May use unformatted file / array to store the result].

Algorithm:

First ()-

If x is a terminal, then $\text{FIRST}(x) = \{ 'x' \}$

If $x \rightarrow \epsilon$, is a production rule, then add ϵ to $\text{FIRST}(x)$.

If $X \rightarrow Y_1 Y_2 Y_3 \dots Y_n$ is a production,

$\text{FIRST}(X) = \text{FIRST}(Y_1)$

If $\text{FIRST}(Y_1)$ contains ϵ then $\text{FIRST}(X) = \{ \text{FIRST}(Y_1) - \epsilon \} \cup \{ \text{FIRST}(Y_2) \}$

If $\text{FIRST}(Y_i)$ contains ϵ for all $i = 1$ to n , then add ϵ to $\text{FIRST}(X)$.

Follow ()-

$\text{FOLLOW}(S) = \{ \$ \}$ // where S is the starting Non-Terminal

If $A \rightarrow pBq$ is a production, where p, B and q are any grammar symbols, then everything in $\text{FIRST}(q)$ except ϵ is in $\text{FOLLOW}(B)$.

If $A \rightarrow pB$ is a production, then everything in $\text{FOLLOW}(A)$ is in

$\text{FOLLOW}(B)$. If $A \rightarrow pBq$ is a production and $\text{FIRST}(q)$ contains ϵ , then $\text{FOLLOW}(B)$ contains $\{ \text{FIRST}(q) - \epsilon \} \cup \text{FOLLOW}(A)$

Program:

```
import sys
sys.setrecursionlimit(60)
def first(string):
    #print("first({})".format(string))
    first_ = set()
    if string in non_terminals:
        alternatives = productions_dict[string]
        for alternative in alternatives:
